

§2. The K-theory associated to a ring. Let

$A$  be a ring with unit but not necessarily commutative.

Let  $GL(A)$  be the infinite general linear group

(inductive limit of  $GL_n(A)$ ) and let  $E(A)$  be the subgroup

generated by <sup>the</sup> elementary matrices. <sup>(Bass [1])</sup>  ~~$GL(A)$~~

~~$BGL(A)$~~  Let  $BGL(A)$  be a classifying space

for  $GL(A)$  which is a <sup>(pointed)</sup> CW complex. Since  $E(A) \subset$

$GL(A) = \pi_1 BGL(A)$  is perfect we may kill it

as in the preceding section obtaining a <sup>(pointed CW)</sup>  ~~$BGL(A)$~~  complex

$$BGL(A)^+ = BGL(A)/E(A)$$

unique up to homotopy type. <sup>We define the algebraic K-</sup>  ~~$BGL(A)$~~  groups

~~$K_i A$~~  ~~of the ring  $A$~~  by setting

$$K_i A = \pi_i BGL(A)^+ \quad i \geq 1$$

and  ~~$K_0 A$~~  taking  $K_0 A$  to be the Grothendieck

group of finitely-generated projective  $A$ -modules.

since  $E(A)$  is normal in  $GL(A)$ , 1.2(i) shows that  $K_1 A = GL(A)/E(A)$ , so our  $K_1$  coincides with that of Bass <sup>[1]</sup>. By 1.2(ii) there is a cartesian square

$$\begin{array}{ccc} BE(A) & \xrightarrow{f'} & BE(A)^+ \\ \downarrow & & \downarrow g \\ BGL(A) & \xrightarrow{f} & BGL(A)^+ \end{array}$$

~~where~~ where  $g$  is the universal covering <sup>(map)</sup> of  $BGL(A)^+$  and where  $f'$  induces isomorphisms on

homology. Hence ~~by~~ <sup>by</sup> the Hurewicz theorem ~~the~~

$$\begin{aligned} K_2 A &= \pi_2 BE(A)^+ = H_2 BE(A)^+ \\ &= H_2 BE(A) \end{aligned}$$

showing that our  $K_2$  coincides with the one defined by Milnor [1].

The following ~~text illustrates the relation~~ ~~give an example~~

illustrates ~~illustrating~~ the relation of our K-groups to those of topological K-theory. Let  $A = \underline{\text{Hom}}(X, \mathbb{R})$  be the ring of continuous real-valued functions on a compact space  $X$  where <sup>the</sup> (here and below)  $\underline{\text{Hom}}$  denotes the function space with compact-open topology. Then  $GL(A) = \varinjlim_n \underline{\text{Hom}}(X, GL_n \mathbb{R})$

is a topological group in a natural way (at least if we work in the category of compactly-generated spaces)

and we ~~let~~ let  $B^{\text{top}} GL(A)$  ~~be its classifying space~~  $= \varinjlim_n B^{\text{top}} \underline{\text{Hom}}(X, GL_n \mathbb{R})$  be its classifying space, e.g.

as constructed by Segal [ ]. In analogy with the definition of  $K_i A$  ~~we~~ define  $K_i^{\text{top}} A$  for  $i \geq 1$

~~to be~~ the homotopy groups of a space  $B^{\text{top}} GL(A)$  ~~the image of  $\pi_i(B^{\text{top}} GL(A))$  in  $\pi_i(B^{\text{top}} GL(A))$~~

$B^{\text{top}} GL(A)^+$  endowed with a universal arrow

$f: B^{\text{top}} GL(A) \longrightarrow B^{\text{top}} GL(A)^+$  killing  $E(A)$ , or more precisely the image of  $E(A)$  in  $\pi_1 B^{\text{top}} GL(A)$ . But this image is zero since  $E(A)$  is contained in the connected component of  $GL(A)$ , hence we can take  $f$  to be the identity and ~~conclude~~ <sup>conclude</sup> that

$$\begin{aligned}
 K_i^{\text{top}} \underline{\text{Hom}}(X, \mathbb{R}) &= \varinjlim_n \pi_{i-1} \underline{\text{Hom}}(X, \mathbb{R}) \\
 &= KO^{-i}(X) \quad i \geq 1.
 \end{aligned}$$

~~Note that the identity map from  $GL(A)$  with discrete topology to  $GL(A)$  with the topology ~~above~~ ~~induced from the topology~~ ~~of  $GL(A)$~~  ~~induces a homomorphism~~~~

Note that the identity map from  $GL(A)$  with discrete topology to  $GL(A)$  with the <sup>above</sup> topology ~~induced from the topology~~ ~~of  $GL(A)$~~  induces a homomorphism

$$K_i^{\text{top}} \underline{\text{Hom}}(X, \mathbb{R}) \longrightarrow K_i^{\text{top}} \underline{\text{Hom}}(X, \mathbb{R}) = KO^{-i}(X)$$

5  
from the <sup>algebraic</sup> ~~algebraic~~ to the topological K-groups.

Similar things hold with  $\mathbb{C}$  instead of  $\mathbb{R}$ .

Suppose now that  $A$  is a general ring,  
and set

$$\tilde{K}(X; A) = [X, BGL(A)^+].$$

for any pointed connected space  $X$ . The above example shows that  $BGL(A)^+$  is the analogue in algebraic K-theory of the spaces  $BO$  and  $BU$  of topological K-theory, hence ~~so~~ it is reasonable to think of ~~the element~~ an element of  $\tilde{K}(X; A)$  as a virtual vector bundle for the ring  $A$  over  $X$  which is reduced, i.e. restricts over the basepoint to zero.

We are now going to develop the properties of this

6  
algebraic K-functor ~~is analogous to the topological~~ following the example of topological

K-theory as closely as possible.

Let  $P(A)$  denote the additive category of finitely-generated projective (left)  $A$ -modules. By a representations of a group  $G$  over  $A$  we shall mean an object  $P$  of  $P(A)$  endowed with a linear action of  $G$ . By an  $A$ -vector bundle over a space  $X$  we mean a fibre bundle over  $X$  with  $A$ -module structures on the fibres which is locally isomorphic to  $X \times P$  where  $P$  is an object of  $P(A)$  <sup>endowed</sup> with the discrete topology.

For simplicity we suppose from now on that  $X$  is a pointed connected CW complex. Then ~~the~~

7

associating to an  $A$ -vector bundle the natural  
action  
~~of  $\pi_1 X$~~  of  $\pi_1 X$  on the fibre over the basepoint  
gives an equivalence of the category of  $A$ -vector  
bundles over  $X$ , with fibrewise  $A$ -linear maps for morphism,  
with the category of representations of  $\pi_1 X$  over  $A$ .  
So from now on we use this equivalence to identify  
 $A$ -vector bundles and representations of the fundamental  
group.

~~Call~~ Call two representations  $E$  and  $E'$  of  
 $G$  over  $A$  stably isomorphic if ~~there are~~

~~trivial representations  $P$  and  $P'$  such that  $E \oplus P \cong E' \oplus P'$~~   
there are trivial representations  $P$  and  $P'$ , i.e. objects  
of  $P(A)$  with trivial  $G$ -actions, such that  $E \oplus P \cong E' \oplus P'$ .

Denote by  $St(G; A)$  the <sup>(set of)</sup> stable isomorphism classes  
 of representations of  $G$  ~~and by~~  $cl(E)$  the isomorphism class  
 of  $E$ .  $St(G; A)$  inherits an  
 abelian monoid structure from the ~~the~~ direct sum

operation on representations. We call elements of  $St(G; A)$   
stable representations and elements of  $St(\pi_1 X; A)$  stable vector  
bundles over  $X$ .

Let  $E_n A$  be the subgroup of  $GL_n A$

generated by elementary matrices. We claim that

~~By~~ associating to a homomorphism <sup>(of groups)</sup>  $G \rightarrow GL_n A$  the  
 corresponding representation of  $G$  on  $A^n$  gives rise to a

bijection

$$(1) \quad \lim_n \text{Hom}_{\text{gps.}}(G, GL_n A) / E_n A \xrightarrow{\sim} St(G; A).$$

Indeed the map is surjective because ~~for~~ <sup>given</sup> any  
 representation  $E$  there is a trivial representation  $P$

such that  $E \oplus P$  is a representation on a free  $A$ -module.

For injectivity suppose  $u, u'$  are two homomorphisms

$G \rightarrow GL_n A$  giving rise to stably isomorphic representations

$E$  and  $E'$ . We ~~must~~ <sup>must</sup> show  $u$  and  $u'$  become

conjugate in  $GL_N A$  by an element of  $E_N A$  for

some  $N \geq n$ . It will suffice to show  $u$  and

$u'$  are conjugate by an element  $\theta$  of  $GL_N A$ ,

because then they will be conjugate in  $GL_{2N} A$

by  $\theta \oplus \theta^{-1}$ , which belongs to  $E_{2N} A$  by the

Whitehead lemma ~~([1], )~~ ([1], ). We are

given that there exist trivial representations  $P$  and  $P'$   
 $E \oplus P$  and  $E' \oplus P'$  are isomorphic.

~~that  $P$  and  $P'$  are trivial~~ Adding

a further trivial representation we can suppose

$P$  is free. ~~that  $P$  is free~~

~~$A^n \oplus P$  is free, hence isomorphic to  $A^n$ , hence  $E \oplus A^n$~~

~~$A^n \oplus P$  is free~~ As  $E$  and  $E'$  are representations  
isomorphisms of  $A$ -modules  $A^n \oplus P' \simeq A^n \oplus P \simeq A^n$   
on  $A^n$  we have  ~~$A^n \oplus P \simeq A^n$~~   
for some  $m$ , hence adding  $A^n$  to both  $P$  and  $P'$  yields

isomorphism  ~~$A^n \oplus P \simeq A^n$~~   $E \oplus A^m \simeq E' \oplus A^m$ ,

giving the desired element  $\theta$  with  $N = n+m$ .

We <sup>now</sup> define a ~~map~~ map

$$(2) \quad \begin{aligned} \text{St}(\pi_1 X; A) &\longrightarrow [X, \text{BGL}(A)^+]_0 = \tilde{K}(X; A) \\ \text{cl}(E) &\longmapsto \eta[E] \end{aligned}$$

~~which~~ which should be thought of as the map  
associating to <sup>stable</sup> vector bundle the associated reduced virtual  
vector bundle. According to (1) an element  $\text{cl}(E)$   
of  $\text{St}(\pi_1 X; A)$  determines a homomorphism  $\pi_1 X \xrightarrow{u} GL(A)$

which is unique up to conjugacy by elements of  $E(A)$ . Composing the ~~map~~ <sup>map</sup>  $X \rightarrow BGL(A)$  in  $\mathcal{H}_0$  associated to  $u$  with the canonical map  $f: BGL(A) \rightarrow BGL(A)^+$ , which we recall is a quotient <sup>conjugation</sup> for the action of  $E(A)$  on  $BGL(A)$ , we <sup>obtain</sup> a well-defined map  $X \rightarrow BGL(A)^+$  in  $\mathcal{H}_0$  which <sup>will be</sup> ~~is~~ denoted by  $\eta[E]$ .

Unlike topological K-theory where stable vector bundles and reduced virtual bundles are the same, at least over finite complexes, the map (2) in algebraic K-theory is not ~~isomorphism~~ usually an isomorphism, e.g.  $X$  simply-connected. Instead we have the following universal property for the arrow

OKAY

~~necessary to add disjoint union of representable functors  
to get correct statement~~

(2). Denote by  $C_*$  the category of ~~pointed~~ ~~connected~~ connected finite complexes and homotopy classes of basepoint-preserving maps, and call a functor  $F: C^* \rightarrow \text{sets}$  representable if it is of the form  $F(X) = [X, Z]$  for some pointed space  $Z$ .

Proposition 2.1: The arrow (2) <sup>(with  $X$  in  $C$ )</sup> is a

universal morphism of functors from  $X \mapsto St(\pi_1 X; A)$  to a representable functor.

Proof: Let  $A_5$  be the alternating group on 5 letters and embed it in the natural way in  $GL_5(A)$ . Let  $N$  be the ~~the~~ normal subgroup of  $GL(A)$  generated by  $A_5$ . ~~is  $N(A)$  which is  $N$  itself~~

Then ~~the~~  $N$  contains all even permutation matrices, ~~hence~~  $GL(A)/N$  is abelian since given ~~the~~  $x, y \in GL(A)$  there is an even permutation matrix  $p$  such that  $x$  commutes with  $pyp^{-1}$ . Thus  $N$  contains

~~the~~  $(GL(A), GL(A)) = E(A)$ , hence  $N = E(A)$

since  $A_5 = (A_5, A_5) \subset E(A)$ . Consequently  $BGL(A)^+ = BGL(A)/A_5$ .

If we take  $BGL(A)$  ~~to~~ be the realization

of the ~~the~~ semi-simplicial set  $\bar{W}(GL(A))$  (see [1])

then  $BA_5$  ~~be~~ can be regarded ~~as~~ as a sub-complex of ~~the~~

~~Let  $Y_0$  be the 2-skeleton of  $BA_5$ .~~  $BGL(A)$  in a

natural way. Let  $Y_0$  be the 2-skeleton of  $BA_5$ .

Then  $\pi_1 Y_0 = A_5$  is ~~is~~ a simple non-abelian group so by attaching one 2-cell and one 3-cell

~~we~~ we can construct an embedding  $f': Y_0 \rightarrow Y_0^+$

inducing an isomorphism on homology with  $Y_0^+$  a

finite simply-connected pointed complex,

i.e.  $Y_0^+ = Y_0 / A_5$  in the notation of §1.

~~Then we can~~ Then we can

take  $BGL(A)^+ = BGL(A) \cup_{Y_0} Y_0^+$  because the

~~inclusion~~ inclusion map  $f: BGL(A) \rightarrow BGL(A)^+$  satisfies (i) and (ii)

of 1.2. Let ~~be~~  $\{Y_\nu\}$  be the lattice of

finite subcomplexes of  $BGL(A)$  containing  $Y_0$  and set  $Y_\nu^+ =$

$Y_\nu \cup_{Y_0} Y_0^+$ . Then  $BGL(A) = \bigcup Y_\nu$  and  $BGL(A)^+ = \bigcup Y_\nu^+$

so for any ~~any~~  $X$  in  $\mathcal{C}$  we have

$$[X, BGL(A)^{\square}]_0 = \varinjlim_{\nu} [X, Y_{\nu}^{\square}]_0.$$

$$[X, BGL(A)^+]_0 = \varinjlim_{\nu} [X, Y_{\nu}^+]_0.$$

~~Using~~ Using ( ) we have

$$\begin{aligned} St(\pi_1 X; A) &= \text{Hom}_{\text{gpo.}}(\pi_1 X, GL(A)) / E(A) \\ &= [X, BGL(A)]_0 / E(A). \end{aligned}$$

Therefore if  $Z$  is a pointed space

$$\text{Hom}(\overset{St(\pi_1 ?; A)}{\text{[?]}}, [?, Z]_0) \text{ ~~is a natural transformation~~}$$

$$= \text{Hom}([?, BGL(A)]_0 / E(A), [?, Z]_0)$$

$$= \text{Hom}([?, BGL(A)]_0 / A_5, [?, Z]_0)$$

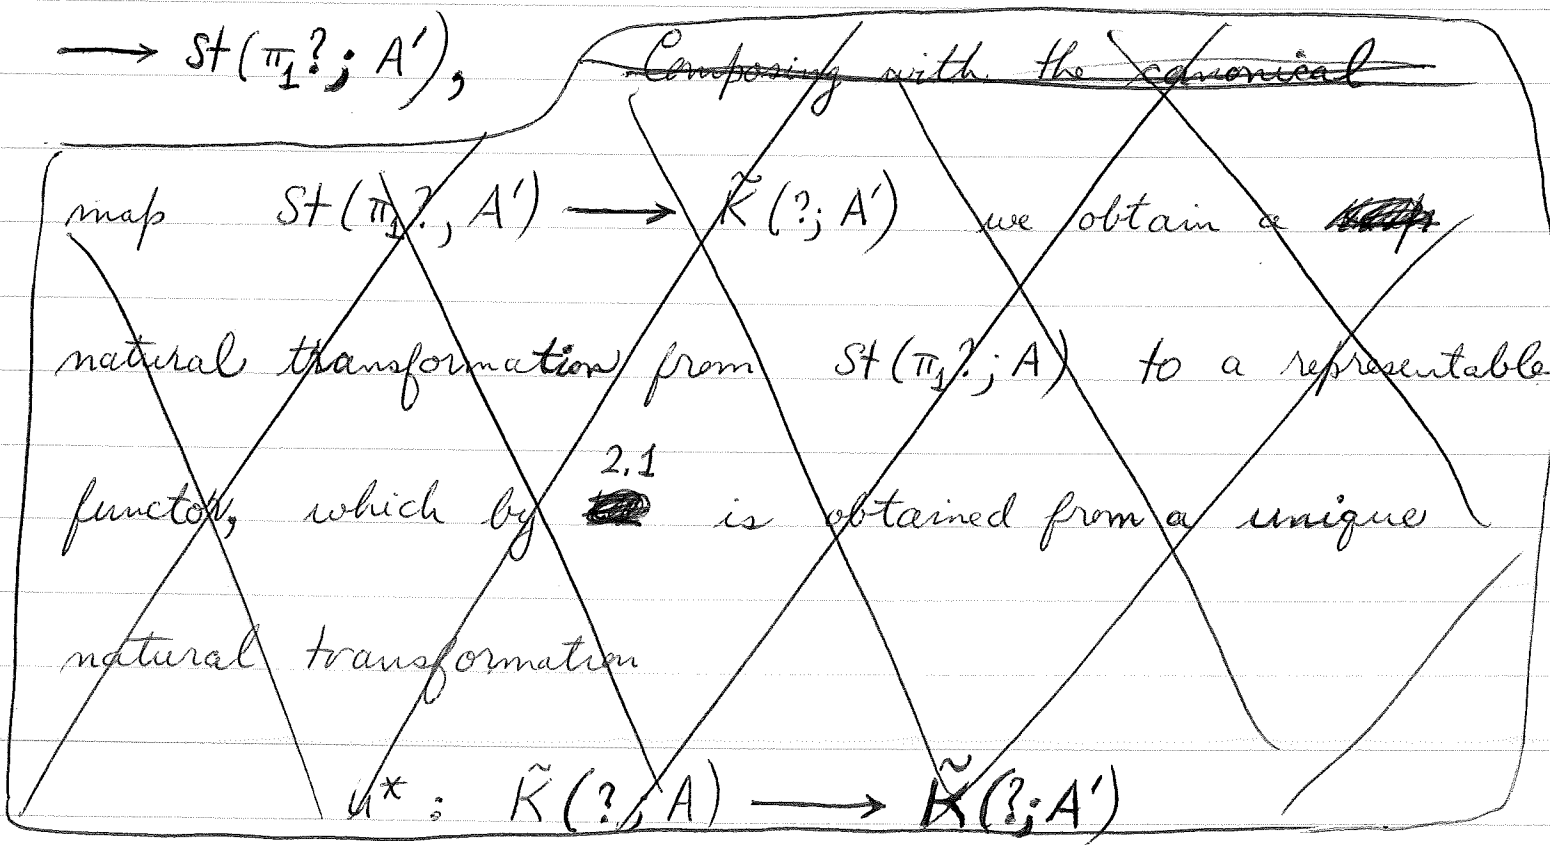

$$= \varprojlim_{\nu} [Y_{\nu}, Z]_0^{A_5}$$

$$= \varprojlim_{\nu} [Y_{\nu}^+, Z]_0$$

$$= \text{Hom}([?, BGL(A)^+]_0, [?, Z]_0)$$

where  $\text{Hom}$  denotes morphisms in the category of functors from  $\mathcal{C}^\circ$  to sets. The proposition follows.

We use ~~this~~ this proposition to extend operations on stable representations to operations on ~~the~~  $\tilde{K}(X, A)$ . For example if  $u: A \rightarrow A'$  is a ring homomorphism, base extension by  $u: E \mapsto A' \otimes_A E$  gives rise to a natural transformation  $u^*: \text{St}(\pi_1?; A) \rightarrow \text{St}(\pi_1?; A')$ ,

~~and~~ and by 2.1 there is a unique natural transformation ~~...~~

~~...~~  $u^*: \tilde{K}(\cdot; A) \rightarrow \tilde{K}(\cdot; A')$  such that the square

$$\begin{array}{ccc}
 St(\pi_1 \cdot; A) & \longrightarrow & St(\pi_1 \cdot; A') \\
 \downarrow & & \downarrow \\
 \tilde{K}(\cdot; A) & \longrightarrow & \tilde{K}(\cdot; A')
 \end{array}$$

commutes. Similarly if  $A'$  is a finitely-generated projective  $A$ -module there is a "restriction of scalars" map

$$u_*: \tilde{K}(\cdot; A') \rightarrow \tilde{K}(\cdot; A).$$

~~...~~  
To handle binary ~~...~~ operations we note that the products of the maps ~~...~~ for

Applying 2.1 to the product  $A \times A'$  of two rings ~~we~~ we see that

$$St(\pi_1 ?; A) \times St(\pi_1 ?; A') \longrightarrow \tilde{K}(?, A) \times \tilde{K}(?, A')$$

is a universal map to a representable functor on  $\mathcal{C}$ , because this arrow is isomorphic to the arrow (2) for  $A \times A'$  since there is an isomorphism in  $\mathcal{H}_0$

$$\begin{aligned} BGL(A \times A')^+ &\simeq \{BGL(A) \times BGL(A')\}^+ \\ &\simeq BGL(A)^+ \times BGL(A')^+ \end{aligned}$$

by 1.5. Consequently any binary, tertiary, etc. operation on stable ~~vector~~ bundles extends ~~uniquely~~ uniquely to the  $\tilde{K}$ -functor. For example the sum operation on

$St(\pi_1 ?; A)$  extends to define an abelian monoid structure on

$\tilde{K}(?; A)$ , the associativity, <sup>(etc.)</sup> of the extension resulting from the ~~uniqueness~~ uniqueness. But one sees quite easily by induction on the number of cells of ~~the~~ the finite complex  $X$  that the monoid  $\tilde{K}(X; A)$  is in fact an abelian group, so we have proved

Proposition 2.2: There is a unique  
abelian group structure on <sup>the functor</sup>  $\tilde{K}(?; A)$  such that  
the canonical <sup>arrow</sup> ~~map~~  $St(\pi_1 ?; A) \rightarrow \tilde{K}(?; A)$  is a  
homomorphism of monoids.

Another way of saying that <sup>the functor</sup>  $\tilde{K}(?; A)$  has a monoid structure is to say that  $BGL(A)^+$  is a weak H-space. ~~One consequence is~~ One consequence is ~~that~~ that  $BGL(A)^+$  is a simple space <sup>(in the sense that</sup> ~~the~~ the fundamental group acts

trivially on  $[X, BGL(A)^+]_0$  for all  $X$  in  $\mathcal{C}$ ,  
or equivalently that

$$[X, BGL(A)^+]_0 = [X, BGL(A)^+].$$

Another consequence is a formula for the  
groups  $K_i A \otimes \mathbb{Q}$  in terms of the rational  
homology of  $GL(A)$ .

Proposition 2.3: The Hurewicz homomorphism

for  $BGL(A)^+$  ~~induces~~ induces an isomorphism  
of  $K_i A \otimes \mathbb{Q}$  with the subspace of primitive elements of degree  $i$   
of the Hopf algebra  $H_*(BGL(A), \mathbb{Q})$ .

~~This is the natural isomorphism of the Hopf algebra  $H_*(BGL(A), \mathbb{Q})$  with the subspace of primitive elements of degree  $i$  of  $H_*(BGL(A), \mathbb{Q})$ . This may be proved by the argument of ~~the~~ which follows from the theorem of Milnor and Moore ([9, appendix])~~

This follows from a theorem of Milnor and Moore ([ ], appendix), or more precisely from their argument which one can check works for weak H-spaces.

Remark 2.4: Actually  $BGL(A)^+$  is a homotopy commutative and associative H-space, in fact it is an infinite loop space as we shall prove later ~~by relating it to Segal's theory [ ]~~ by relating it to Segal's theory [ ]. On a more elementary level one can define the product on  $BGL(A)^+$  to be the one induced by ~~the embedding of  $GL(A) \times GL(A)$  into  $GL(A)$~~  the embedding of  $GL(A) \times GL(A)$  into  $GL(A)$  which one obtains from ~~enumerating  $\mathbb{N}^+ \perp \mathbb{N}^+$~~  enumerating  $\mathbb{N}^+ \perp \mathbb{N}^+$ , where  $\mathbb{N}^+$  is the

set of positive integers. To prove the unitarity, associativity, and commutativity one can use the following lemma which we state without proof.

~~Lemma: Let  $u: BGL(A)^+ \rightarrow BGL(A)^+$  be the map in  $\mathcal{H}_0$  induced by the embedding of  $GL(A)$  into  $BGL(A)$  obtained from an injection  $\mathbb{N}^+ \rightarrow \mathbb{N}^+$ . Then~~

Lemma: Let  $u: GL(A) \rightarrow GL(A)$  be the embedding ~~associated to~~ associated to an injection of  $\mathbb{N}^+$  into  $\mathbb{N}^+$ . Then the triangle in  $\mathcal{H}_0$

is commutative ~~is~~.
