CUDA Programming on NVIDIA GPUs Mike Giles

Practical 1: Getting Started

This practical gives a gentle introduction to CUDA programming using a very simple code. The main objectives in this practical are to learn about:

- the way in which an application consists of a host code to be executed on the CPU, plus kernel code to be executed on the GPU
- how to copy data between the graphics card (device) and the CPU (host)
- how to include error-checking, and printing from a kernel

The practicals are to be carried out on the ARC-HTC system.

Before starting, please read the notes at

https://people.maths.ox.ac.uk/gilesm/cuda/arc_notes.pdf.

(If you are reading this PDF document online, the link above should appear in blue and you can click on it to go to the notes.)

What you are to do is as follows:

- 1. Copy all of the course files to your home directory, following the directions given in the notes.
- 2. The two codes prac1a and prac1b are in the same directory prac1. They are compiled and linked by the command

make

which carries out the steps within the Makefile.

- 3. Read through the prac1a.cu source file and compare it to the prac1b.cu source file which adds in error-checking.
- 4. Run both codes using the batch submission scripts supplied.
- 5. Try introducing errors into both prac1a.cu and prac1b.cu, such as trying to allocate too much memory (e.g. by specifying an enormous value like (long long) 50000000000), or setting nblocks=0 or nthreads=10000, and see what happens.

- 6. Add a printf statement to the kernel routine my_first_kernel, for example to print out the value of tid. Note that the new output may be written to the screen after the existing output from the main code, because it gets put into a write buffer which is flushed only intermittently.
- 7. Modify prac1b.cu to add together two vectors which you initialise on the host and then copy to the device. This will require additional memory allocation and two memcpy operations to transfer the vector data from the host to the device.
- 8. There is a third version of the original code, praclc.cu, which uses "managed memory" on top of Unified Memory. Read through the code to see what it does, and try compiling and running it.
- 9. If you have spare time, you can browse through the online info on NVIDIA's sample codes which are on GitHub at https://github.com/nvidia/cuda-samples.
